## The Physics Reach of BTeV

BTeV was recently described by unanimous decision of the P5 committee as

"potentially the best quark flavor physics experiment into the next decade"

## The P5 recommendation:

"P5 supports the construction of BTeV as an important project in the world-wide flavor physics area. Subject to constraints within the HEP budget, we strongly recommend an earlier BTeV construction profile and enhanced C0 optics"
B. Cox

## Objectives of BTeV

Comprehensive study of band c quark production, mixing, decays

- new physics in measurements of CP phases in b and c quark decays
- new physics in detection of rare band c decays
- precision measurement of CKM matrix elements
- b and c quark production
- structure of b baryonic states
- $\boldsymbol{B}_{\text {s decays }}$
B. Cox

## B Physics at

## Hadron Colliders

- The Opportunity
- The Tevatron, at $10^{32}$, produces $10^{11} \mathrm{~b}$-pairs/year
- It is a "High Luminosity B Factory" due to the broadband vertex trigger, giving access to $B_{d}, B_{u}, B_{s}$, bbaryon, and $B_{c}$ states.
- Because you are colliding gluons, it is intrinsically asymmetric so time evolution studies are possible (and integrated asymmetries are nonzero)
- The Challenge
- The b events are accompanied by a very high rate of background events
- The b's are produced over a very large range of momentum and angles
- Even in the b events of interest, there is a complicated underlying event so one does not have the stringent constraints that one has in an $\mathrm{e}^{+} \mathrm{e}^{-}$machine

## Anticipated Properties of the Tevatron

Luminosity
b cross-section
\# of b-pairs per $10^{7}$ sec
b fraction.
c cross-section
Bunch Spacing
Luminous region length
Luminous region width Interactions/crossing
$2 \times 10^{32}$
$>100 \mu \mathrm{~b}$
$2 \times 10^{11}$
$2 \times 10^{-3}$
$>500 \mu \mathrm{~b}$
396 ns
$\sigma_{\mathrm{z}}=30 \mathrm{~cm}, \sigma_{\mathrm{x}} \sim \sigma_{\mathrm{y}} \sim 50 \mu \mathrm{~m}$
<2.0>

Operation at 396 ns
Bunch Crossing

- BTeV was designed for $\mathrm{L}=2 \times 10^{32} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$ at 132 ns or $\langle 2\rangle \mathrm{int} /$ crossing
- Now expect $\mathrm{L} \sim 2.0 \times 10^{32} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$ at 396 ns , i.e. $\langle 6\rangle$ int/crossing or $\mathrm{L} \sim 1.3 \times 10^{32} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$ at 396 ns , i.e. $\langle 4\rangle \mathrm{int} /$ crossing
- Verified performance by repeating many of the simulations at $\langle 4\rangle$ and $\langle 6\rangle$ int/crossing (without re-optimizing the code) Average impact across store is $\sim 10 \%$
- Key potential problems areas - trigger, EMCAL and RICH all hold up well based on simulations
- Ongoing work to understand fully the impact of a change to 396 ns bunch spacing.

## Trigger Performance

- For a requirement of at least 2 tracks detached by more than 60 , only $1 \%$ of the beam crossings have interactions that satisfy the BTeV trigger.
- The BTeV trigger has the following efficiencies for these states:

| State | efficiency $(\%)$ | state | efficiency(\%) |
| :--- | :---: | :--- | :--- |
| $\mathrm{B} \rightarrow \pi^{+} \pi^{-}$ | 63 | $\mathrm{~B}^{\circ} \rightarrow \mathrm{K}^{+} \pi^{-}$ | 63 |
| $\mathrm{~B}_{\mathrm{s}} \rightarrow \mathrm{D}_{\mathrm{s}} \mathrm{K}$ | 74 | $\mathrm{~B}^{\mathrm{o}} \rightarrow \mathrm{J} / \psi \mathrm{K}_{\mathrm{s}}$ | 50 |
| $\mathrm{~B}^{-} \rightarrow \mathrm{D}^{\circ} \mathrm{K}^{-}$ | 70 | $\mathrm{~B}_{\mathrm{s}} \rightarrow \mathrm{J} / \psi \mathrm{K}^{*}$ | 68 |
| $\mathrm{~B}^{-} \rightarrow \mathrm{K}_{\mathrm{s}} \pi^{-}$ | 27 | $\mathrm{~B}^{\circ} \rightarrow \mathrm{K}^{*} \gamma$ | 40 |

At $<2>$ interactions per crossing

## Flavor Tagging in BTeV

¥ $\quad \varepsilon \equiv$ efficiency

- $\mathrm{D} \equiv$ Dilution or $\left(\mathrm{N}_{\text {right }}-\mathrm{N}_{\text {wrong }}\right) /\left(\mathrm{N}_{\text {right }}+\mathrm{N}_{\text {wrong }}\right)$
- Effective tagging efficiency $\equiv \varepsilon \mathrm{D}^{2}$
- Extensive study for BTeV uses
- Opposite sign $\mathrm{K}^{ \pm}$
- Jet Charge
- Same side $\pi^{ \pm}$(for $\mathrm{B}^{\circ}$ ) or $\mathrm{K}^{ \pm}$for $\left(\mathrm{B}_{\mathrm{s}}\right)$
- Leptons
- Conclusion:
$\varepsilon D^{2}\left(B^{0}\right)=0.10 \quad \varepsilon D^{2}\left(B_{s}\right)=\mathbf{0 . 1 3}$,
(difference due to same side tagging)
B. Cox

## The CKM Phases

 (Angles)$$
\begin{array}{ll}
\beta=\arg \left(-\frac{\mathrm{V}_{\mathrm{t}} \mathrm{~V}_{\mathrm{td}}^{*}}{\mathrm{~V}_{\mathrm{cb}} \mathrm{~V}_{\mathrm{cd}}^{*}}\right) & \gamma=\arg \left(-\frac{\mathrm{V}_{\mathrm{ub}}^{*} \mathrm{~V}_{\mathrm{ud}}}{\mathrm{~V}_{\mathrm{cb}}^{*} \mathrm{~V}_{\mathrm{cd}}}\right) \\
\chi=\arg \left(-\frac{\mathrm{V}_{\mathrm{cs}}^{*} \mathrm{~V}_{\mathrm{cb}}}{\mathrm{~V}_{\mathrm{ts}}^{*} \mathrm{~V}_{\mathrm{tb}}}\right) & \chi^{\prime}=\arg \left(-\frac{\mathrm{V}_{\mathrm{ud}}^{*} \mathrm{~V}_{\mathrm{us}}}{\mathrm{~V}_{\mathrm{cd}}^{*} \mathrm{~V}_{\mathrm{cs}}}\right)
\end{array}
$$

$\alpha=\pi-(\beta+\gamma), \beta \& \gamma$ probably large, $\chi$ small $\sim 0.03 \chi^{\prime}$ smaller

## verbtev

## Current Status of

## Knowledge of $\rho, \eta$

- Constraints on $\rho \& \eta$ from Hocker et al.
- Theory parameters are allowed to have equal probability within a restricted but arbitrary range

- Large model dependence for $V_{u b} / V_{c b}, \varepsilon_{K}$ and $\Delta m_{d}$,
- Smaller but significant model dependence for $\Delta m_{s}$.
- Virtually no model dependence for $\sin (2 \beta)$

Primary Modes

- $\mathbf{B}^{0} \rightarrow \mathbf{J} / \Psi \mathrm{K}_{\mathrm{s}}$
- $\mathbf{B}^{0} \rightarrow \rho \pi \rightarrow \pi^{+} \pi \pi^{0}$
- $\mathbf{B}_{\mathrm{s}} \rightarrow \mathbf{D}^{ \pm} \mathbf{K}^{\boldsymbol{+}}$
- $\mathrm{B}^{-} \rightarrow \mathrm{D}_{\mathrm{s}}^{0} \mathrm{~K}^{-}$(and c.c.)
- $\mathbf{B}_{\mathrm{s}} \rightarrow \mathrm{J} / \Psi \eta^{\prime}$
$\sin (2 \beta)$
$\sin (2 \alpha)$
$\sin (\gamma)$
$\sin (\gamma)$
$\sin (2 \chi)$

## verbtev

## Measuring $\boldsymbol{\alpha}$

## Using $\boldsymbol{B}^{\boldsymbol{o}} \rightarrow \boldsymbol{\pi}^{+} \boldsymbol{\pi}^{-}$

- Using $B^{0} \rightarrow \pi^{+} \pi$ has the problem of a large Penguin term (CLEO+BABAR+BELLE):

$$
\begin{aligned}
& \mathrm{B}\left(\mathrm{~B}^{0} \rightarrow \pi^{+} \pi^{-}\right)=(4.5 \pm 0.9) \times 10^{-6} \\
& \mathrm{~B}\left(\mathrm{~B}^{0} \rightarrow \mathrm{~K}^{ \pm} \pi^{\mathrm{m}}\right)=(17.3 \pm 1.5) \times 10^{-6}
\end{aligned}
$$

- The effect of the Penguin must be measured in order to determine $\alpha$. Can be done using Isospin, but requires a rate measurements of $\pi \pi^{\circ}$ and $\pi^{0} \pi^{0}$ (Gronau \& London). However, this is complicated.

B. Cox

## verbtev

## Measuring $\alpha$

## Using $B^{o} \rightarrow \rho \pi \rightarrow \pi^{+} \pi \pi^{0}$

- A Dalitz Plot analysis gives both $\sin (2 \alpha)$ and $\cos (2 \alpha)$
(Snyder \& Quinn)
- Measured branching ratios are:
$B\left(B^{-} \rightarrow \rho^{\circ} \pi^{-}\right)=\sim 10^{-5}$
$B\left(B^{0} \rightarrow \rho^{-} \pi^{+}+\rho^{+} \pi^{-}\right)=\sim 3 \times 10^{-5}$
$B\left(B^{0} \rightarrow \rho^{0} \pi^{0}\right)<0.5 \times 10^{-5}$
- BTeV simulations indicate that 1000-tagged events are sufficient to determine $\alpha$ with an error $\delta \alpha \sim 4^{0}$.

B. Cox

## Detecting $B^{o} \rightarrow \rho \pi$

Based 9.9x10 ${ }^{6}$ background events

$$
\begin{aligned}
& \mathrm{B}^{0} \rightarrow \mathrm{\rho}^{+} \pi-\mathrm{S} / \mathrm{B}=4.1 \\
& \mathrm{~B}^{0} \rightarrow \mathrm{\rho}^{\circ} \pi^{0} \\
& \mathrm{~S} / \mathrm{B}=0.3
\end{aligned}
$$

B. Cox

## verbtev

$\boldsymbol{B}^{-} \rightarrow \boldsymbol{D}^{0} \mathbf{K}^{-} \rightarrow\left[K^{+} \pi\right] \boldsymbol{K}^{-}$
$\boldsymbol{B}^{-} \rightarrow \boldsymbol{D}^{0} \mathbf{K}^{-} \rightarrow\left[{K^{+}}^{+}\right] K^{-}$
Model independent
Decay processes

## Rate difference between $\mathbf{B}^{-} \rightarrow \mathbf{D}^{0} \mathbf{K}^{-} \boldsymbol{\&} \mathbf{B}^{+} \rightarrow \mathbf{D}^{0} \mathbf{K}^{+}$

$$
B \sim 1 \times 10^{-7}
$$

$\mathrm{B} \sim \mathbf{0 . 7 \times 1 0}{ }^{-7}$
B. Cox

## Other ways of

## Measuring $\gamma$

- There are two more ways of determining $\gamma$
- Rate measurements in $\mathrm{K}^{\circ} \pi^{ \pm}$and $\mathrm{K}^{ \pm} \pi^{\mathrm{m}}$ (Fleisher-Mannel) or rates in $K^{\circ} \pi^{ \pm}$\& asymmetry in $K^{ \pm} \pi^{0}$ (Neubert-Rosner, Beneke et al). Has theoretical uncertainties.
- Use U spin symmetry $\mathrm{d} \Leftrightarrow \mathrm{s}$ : measure time dependent asymmetries in both $\mathrm{B}^{0} \rightarrow \pi^{+} \pi^{-} \& \mathrm{~B}_{\mathrm{s}} \rightarrow \mathrm{K}^{+} \mathrm{K}^{-}$(Fleischer).
- Ambiguities here as well but they are different in each method, and using several methods can resolve them.
verbtev

## $x_{s}$ Reach

- BTeV reaches sensitivity to $\mathrm{x}_{\mathrm{s}}$ of $\mathbf{8 0}$ in 3.2 years

Using
$\mathrm{B}_{\mathrm{s}} \rightarrow \mathrm{D}_{\mathrm{s}} \pi$

October 18, 2003

B. Cox

## Measuring $\chi$

- BTeV can use CP eigenstates in $B_{s}$ decay to measure $\chi$, for example
$\left.-\quad B_{s} \rightarrow \mathrm{~J} / \psi \eta^{( }\right), \eta \rightarrow \gamma \gamma, \eta^{\prime} \rightarrow \rho \gamma$
- Can also use $J / \psi \phi$, but need
- a complicated angular analysis

Note: Silva \& Wolfenstein (hep-ph/9610208), (Aleksan, Kayser \& London), propose a test of the SM, that can reveal new physics; it relies on measuring the angle $\chi$.
The critical check is $\quad \sin \chi=\lambda^{2}\left(\frac{\sin \beta \sin \gamma}{\sin (\beta+\gamma)}\right)$
Very sensitive since $\boldsymbol{\lambda}=\mathbf{0 . 2 2 0 5} \pm \mathbf{0 . 0 0 1 8}$; Since $\boldsymbol{\chi} \sim \mathbf{0 . 0 3}$, lots of data needed

## Current Constraints on New Physics

- All our current measurements are a combination of SM and New Physics-any proposed Models must satisfy current constraints
- SM tree level diagrams are probably large; consider them a background to New Physics.
- Loop diagrams \& CP violation are the best places to see New Physics.
- The most important constraints are
- neutron electric dipole moment $<6.3 \times 10^{-26} e \mathrm{~cm}$
$-\mathrm{B}(\mathrm{b} \rightarrow \mathrm{s} \gamma)=(2.88 \pm 0.39) \times 10^{-4}$
- CP violation in $\mathrm{K}_{\mathrm{L}}$ decay, $\varepsilon_{\mathrm{K}}=(2.271 \pm 0.017) \times 10^{-3}$
- $\mathrm{B}^{\mathrm{o}}$ mixing parameter $\Delta \mathrm{m}_{\mathrm{d}}=(0.487 \pm 0.014) \mathrm{ps}^{-1}$

## Relevance of B Physics

 for New Physics Searches- $\quad \mathrm{BTeV}$ is sensitive using b and c decays in loop diagrams to mass scales $\sim$ few TeV depending on couplings (model dependent). The New Physics effects in these loops may be the only way to distinguish among models.
- Masiero \& Vives: "the relevance of SUSY searches in rare processes is not confined to the usually quoted possibility that indirect searches can arrive 'first' in signaling the presence of SUSY. Even after the possible direct observation of SUSY particles, the importance of FCNC \& CPV in testing SUSY remains of utmost relevance. They are \& will be complementary to the Tevatron \& LHC establishing low energy supersymmetry as the response to the electroweak breaking puzzle" (hep-ph/0104027)

## BTeV Charm Physics Reach

- $D^{0}-D^{0}$ Mixing: Box diagram: $\Delta m_{D}{ }^{S D} / \Gamma<1 \times 10^{-4}$

LD Dispersive: $\Delta m_{D}{ }^{L D} / \Gamma \sim 2 \times 10^{-4}$
LD HQET: $\quad \Delta m_{D}{ }^{L D} / \Gamma \sim(1$ to 2$) \times 10^{-5}$
SM Contribution: $\Delta m_{D}{ }^{S M} / \Gamma<1 \times 10^{-4}$
Current experimental limit $\Delta m_{D} / \Gamma<0.1$ Lots of Discovery room!

- CP Violation: Possibly observe SM CP violation in charm!
$S M: A_{C P} \approx 2.8 \times 10^{-3}$ for $D^{+} \rightarrow K^{* 0} K^{+}$
$A_{C P} \approx-8.1 \times 10^{-3}$ for $D_{s}^{+} \rightarrow K^{*+} \eta^{\prime}$
Expect $\sigma\left(A_{C P}\right)=1 \times 10^{-3}$ for $10^{6}$ background-free events
Excellent D* tag (efficiency $\approx 25 \%$ )
Geant simulation gives \# reconstructed $D^{0} \rightarrow K \pi>10^{8}$
BTeV can do charm physics!

## BTeV vs. Super BABAR

- $\mathrm{L}=10^{36}$ is the goal of Super BABAR (>100 times original design).
- This would compete with BTeV in $B^{0} \& B^{-}$physics, but not in $B_{s}$
- Still could not do $B_{s}, B_{c}$, and $\Lambda_{b}$
- Problems
- Machine: M2 review at Snowmass (S. Henderson) said:
"Every parameter is pushed to the limit-many accelerator physics \& technology issues"
- Detector: Essentially all the BABAR subsystems would need to be replaced to withstand the particle densities \& radiation load; need to run while machine fills continuously.

## BTeV vs. Super KEK

- KEK-B plans for $\mathrm{L}=10^{35}$ in 2007 (10 x original design).
- However \#'s in previous tables are still not competitive with BTeV
- E2 report at Snowmass: Problems for the detector due to higher occupancies, trigger rates, synchrotron radiation, increased pressure in the interaction region \& larger backgrounds at injection.
- Problem areas include: silicon vertex detector, CSI(TI) EM calorimeter because it is slow, and Muon RPC's that already have dead-time losses

Relative to $\mathbf{L H C b}$<br>disadvantages advantages

- LHCb has much higher B cross section (~ factor of 5)
- LHCb has three times lower interaction per crossing.
- BTeV has lower total cross section (factor of 1.6 lower)
- BTeV has vertex detector in magnetic field which allows rejection of high multiple scattering (low $\mathbf{p}$ ) tracks in the trigger
- BTeV is designed around a pixel vertex detector which has much less occupancy, and allows for a detached vertex trigger in the first trigger level.
- Important for accumulation of large samples of rare hadronic decays and charm physics.
- Allows BTeV to run with multiple interactions per crossing, $L$ in excess of $2 \times 10^{32} \mathrm{~cm}^{-2} \mathrm{~s}^{-1}$
- BTeV will have a much better EM calorimeter
- BTeV is planning to read out $5 x$ as many b's/second

Toroids

Slicon Strips

Calorimeter

Comparison of BTeV with LHCb (from LHCb TDR)

## Summary

As the patron saint of Virginia Thomas Jefferson would say, "We hold these truths to be self evident....."

- The BTeV experiment offers a very sensitive way study CP violation and search for new physics in broad spectrum of $B$ and $C$ decays in the coming time period.
- Comparisons with the most ambitious $e^{+} e^{-}$opportunities, even if they can be built, are still favorable to BTeV.
- BTeV when compared with LHCb has significant advantages when the better calorimetry and the broader spectrum of charm and beauty physics made possible by the vertex trigger is taken into account.
- Now that the P5 report has been issued, we hope to proceed expeditiously with the necessary $\boldsymbol{R \&} \&$ and construction to meet the Fermilab schedule of first beam for BTeV in early 2009.

Caveat:

## Ambiguities

- A measurement of $\sin (2 \beta)$ using $\psi K_{s}$ still results in a 4 fold ambiguity- $\beta, \pi / 2-\beta, \pi+\beta, 3 \pi / 2-\beta$
- Only reason $\eta>0$, is $B_{k}>0$ from theory, and related theoretical interpretation of $\boldsymbol{\varepsilon}^{\boldsymbol{\prime}}$
